

COMPOSITE MATERIAL

CROSS REFERENCE TO RELATED APPLICATIONS

This application is the US national phase of PCT
5 application PCT/DE2003/003228 filed 26 September 2003 with a claim
to the priority of German patent application 10246635.1 itself filed
7 October 2002 and German patent application 10251404.6 itself filed
5 November 2002.

FIELD OF THE INVENTION

10 The invention relates to a composite material of a base
body with a multi-layer coating. Such composite bodies are, for
example, used as cutting inserts for machining purposes, namely,
turning, milling or boring. The base bodies, to which the coating
can be applied by physical or chemical vapor deposition processes
15 (PVD or CVD), can be composed of hard metal, a cermet, steel or a
ceramic.

BACKGROUND OF THE INVENTION

DE 27 36 982 A1 already describes a wear resistant coating
for shaped parts, especially for tools, comprised of a shaped body,
20 preferably of hard metal, and one or more surface coatings, at least
one of which is a protective layer with a ceramic matrix into which
a further material is incorporated. The ceramic matrix and the
material incorporated therein have different coefficients of thermal
expansion so that the protective layer is subject to the formation
25 of fine microcracks therein. Unstabilized and/or partially
stabilized ZrO₂ has been proposed as the material incorporated into
the interstices of a ceramic matrix of Al₂O₃. To produce such a layer

by the CVD process, AlCl_3 , CO_2 and H_2 are admitted as a gas phase into a reaction vessel at 1100°C to produce Al_2O_3 or ZrCl_4 and water vapor (H_2O) are admitted to produce ZrO_2 . Because of the density difference between the tetragonal modification of ZrO_2 formed at temperatures above the transformation temperature of about 1100°C and the monoclinic modification formed below about 1100°C , with a corresponding phase conversion there can be a significant change in volume of the deposited ZrO_2 . As a consequence, with increasing volume proportions of the ZrO_2 there is a simultaneous increase in the microcrack density in the deposited ceramic layer.

In DE 28 25 009 C2 (US equivalent 4,180,400), a hard metal body with a thin wear-resistant surface layer of Al_2O_3 has been described and which is composed completely or at least 85% of the κ -modification and any possible remainder of the α -modification, forming surface regions or patches at most $10\mu\text{m}$ in size. The aluminum oxide layer can contain further additions of titanium, zirconium and/or hafnium. To create this ceramic layer by the CVD process, the gas mixture apart from AlCl_3 , CO_2 , CO and H_2 has also small amounts of 0.03 to 0.5% TiCl_4 added to it. This addition, however, serves exclusively or nearly exclusively for the formation of the κ - Al_2O_3 phase.

A further CVD process for depositing Al_2O_3 and/or ZrO_2 using additional reagents, like hydrogen sulfide, has been described in EP 0 523 021 B1 (US equivalent 5,674,564).

DE 195 18 927 A1 (US equivalent 5,827,570) describes a coated cutting tool comprised of a substrate of sintered carbide or ceramic with a wear-resistant composite ceramic coating which has

two different metal oxide phases, for example of Al_2O_3 and ZrO_2 , and in addition thereto a doping agent selected from the group of sulfur, selenium, tellurium, phosphorus, arsenic, antimony, bismuth or compounds of these elements. To produce this two-phase layer by a CVD process, for example $AlCl_3$ and $ZrCl_4$, CO_2 with H_2 as a carrier gas, in addition to an H_2S gas, is passed over the substrate body at a temperature of about 700° to $1250^\circ C$ and a pressure from 133Pa to ambient pressure, whereby the two-phase layer with the doping agent is deposited.

EP 0 786 536 A1 (US equivalent 5,985,427) describes a coated hard metal body with a 3 to 30 μm thick aluminum oxide coating which has been deposited by means of CVD and/or PVD and contains 0.005 to 0.5 weight % chlorine. Optionally 0.5 to 10 weight % Zr and/or Hf and 1.5 to 15 weight % Ti can be contained in this coating.

EP 0 162 656 A2 (US equivalent 4,746,563) describes a multilayer coating on a hard metal substrate body which is comprised of an inner layer, which is composed of at least one carbide, nitride, carbonitride, carbo-oxygen nitride, oxynitride, boron nitride or boron carbo nitride of titanium, and an outer multilayer coating with a total thickness of 5 to 20 μm and provided with an outer layer of a plurality of Al_2O_3 coatings with a respective thickness of 0.01 to 2 μm and each comprised of an Al_2O_3 film in which titanium oxide has been dissolved or which has been codeposited with at least 30 volume percent titanium oxide. The layers are separated by intervening layers with respective thicknesses of 0.01 to 2 μm and which each can comprise TiC , TiN ,

TiCN, TiCNO, TiNO, titanium oxides, Ti(B,N), Ti(B,N,C), SiC, AlN or ALON.

In WO 00/17 416 (US equivalent 6,660,371), a composite material of a coated hard metal or cermet base body has been described on which the single layer or a multilayer coating is applied at least in the form of a 0.5 μm to 25 μm thick coating and preferably the outermost phase is an Al_2O_3 phase containing a ZrO_2 and/or HfO_2 phase which in turn contains a third fine dispersive phase consisting of an oxide, oxycarbide, oxynitride or oxycarbonitride of titanium. The proportion of the third phase in the overall composition of this layer amounts to 0.2 to 5 mol %. To produce such a three phase layer, a CVD process with deposition temperatures between 900°C and 1000°C is selected in which the gases required for the deposit contain chlorides of the Al, Zr and Hf, and in addition CO_2 , H_2 , CH_4 and N_2 or inert gas under pressures of 10 to 100,000 Pa. The TiO_x incorporated as the third phase has a positive effect on the growth speed and on the particle sizes of the aluminum oxide and zirconium or hafnium oxide. Preferably a coating temperature of 960°C is selected in which the ZrO_2 is present in the monoclinic form. From the mentioned publication, therefore, hard metal substrate bodies are known which have layer sequences TiN-Ti(C,N) and the described three phase layer.

OBJECT OF THE INVENTION

It is the object of the present invention to provide a composite body which, when used as a cutting insert, affords increased cutting effectivity as well as a longer useful life. Higher cutting effectiveness is determined in terms of the desired

high cutting speeds and increased thicknesses of the chip removed. If possible such cutting inserts should be usable in so-called dry cutting operations.

SUMMARY OF THE INVENTION

5 These objects are attained with a composite material having a base body carrying at least one multiphase coating of the oxides of aluminum, zirconium and/or hafnium and of titanium (as a three phase coating) and a single-phase layer or coating of Al_2O_3 , ZrO_2 or HfO_2 . In the coating on the base body, therefore, there is
10 both at least one multiphase oxide layer as well as at least one single-phase oxide layer. The multiphase layer can, apart from the three mentioned oxide components, contain MgO and the single-phase layer can additionally contain up to 1% of a titanium oxide proportion. According to a further feature of the invention,
15 however, at least two and preferably at least three layers are provided of which each is comprised of the mentioned multiphase layer of the oxides of Al, Zr, Ti and/or Al, Hf, Ti and/or Al, Zr, Ti, Mg and/or Al, Hf, Ti, Mg, and a single-phase oxide layer of an oxide of Hf, Zr or Al. Preferably at least three-phase or four-
20 phase oxide layers are provided between which respective single-phase oxide layers are disposed and whereby a single-phase oxide layer also forms the outer cover coating. These layers have a fine grained lattice structure and a uniform phase distribution and provide a high degree of thermal insulation. The base body can also
25 be comprised of a hard metal, a cermet, or steel or a ceramic material.

Between the substrate body and the first oxide layer which preferably is a multiphase oxide layer is at least one layer of a carbonitride of titanium, hafnium, zirconium. This cover layer can have a thickness between 2 to 15 μm , especially 3 to 8 μm .

5 According to a further feature of the invention it is possible to provide, between the multiphase oxide layer and the single-phase oxide layer, preferably in a multi layer sequence of the multiphase oxide layers and single-phase oxide layers between each of the mentioned layers, one or more intermediate layers of
10 titanium, hafnium or zirconium carbonitride.

These intervening layers have preferably a thickness between 0.2 and 3 μm , especially of 2 μm .

The total thickness of all multiphase oxide layers and all single-phase oxide layers preferably lies between 6 and 20 μm
15 especially at 10 μm . The difference of a single-phase oxide layer can amount to 2 to 6 μm preferably 4 μm and the thickness of an individual single-phase oxide layer can amount to 1 to 5 μm , preferably 3 μm .

The multiphase coating is produced by a CVD process which
20 is basically known from WO 00/17 416 or as the so-called middle temperature CVD process.

In a further embodiment of the invention, to eliminate tensile stresses or to increase compressive stresses in the composite body, the composite body can be subjected to a treatment
25 with a blasting agent, the blasting agent being preferably composed composed of a hard metal granulate which can have a substantially

rounded grain configuration and a maximum grain diameter of 200 μm and more preferably of a maximum of 100 μm .

BRIEF DESCRIPTION OF THE DRAWING

Further advantages of the invention are described in connection with an exemplary embodiment. The drawing shows.

FIGS. 1 to 3 respective diagrams which provide information with respect to the improved life of the composite material according to the invention in cutting inserts by comparison with the state of the art.

SPECIFIC DESCRIPTION

The test objects were in all three cases cutting inserts of the type CNMG120412-5. In all three cases the substrate body was a hard metal (THM) but the coatings were different in the three cases. In a first test series the work piece was gray cast iron with a cutting speed of 450 m/min and a cutting depth of 2.5 mm and an advance of the cutting insert of 0.315 mm per revolution. The first cutting body was comprised of a hard metal base body coated with a two layer coating of TiCN-Al₂O₃ (as an outer layer). The life achieved was less than 2 min. A significantly improved life was given with a two layer coating in which on a TiCN- cover layer a three phase oxide layer according to WO 00/17 416 was applied comprised of Al₂O₃/ZrO₂/TiO₂.

A clear improvement in the useful life still further can however be achieved with a cutting insert which had a TiCN adjacent the substrate body and a six layer outer coating which was comprised of three individual layers each of a three phase oxide coating and a single-phase ZrO₂ layer.

In a second test a gray cast iron workpiece with an extremely rough surface is machined by turning whereby in comparison to the previously described test only the cutting speed was reduced to 200 m/min. Based upon this cutting speed, there was obtained a useful life of 6 min for the cutting inserts with a TiCN-Al₂O₃ coating, of about 7 min for cutting inserts with a TiCN-Al₂O₃/ZrO₂/TiO₂ coating, and a useful life of 9 min for a cutting insert with the coating of the invention in which by contrast with the previously described versions had a three times alteration of a three-phase oxide layer of Al₂O₃/HfO₂/TiO₂ and the single-phase oxide layer of HfO₂. The above described cutting tests were carried out with so-called dry cutting.

As FIG. 3 shows, however, with use of a lubricant coolant, still higher useful lives can be obtained. In the lathe turning of grey cast iron at cutting speeds of 450 m/min, a cutting depth of 2.5 mm, and a feed of 0.315 mm per revolution, the useful life of the cutting insert with a TiCN-Al₂O₃ coating amounted to about 4.5 min, the useful life of a cutting insert with a coating according to WO 00/17 416 was about 6.5 min, whereas the coating according to the invention resulted in useful lives of 10 or 12.5 min. Especially when HfO₂ forms the single-phase oxide layers, it is possible to obtain a still more substantial increase in the useful life by comparison with the already improved life using ZrO₂ as the single-phase oxide layer. All coatings were applied by the so-called CVD-MT (middle temperature) process under the same process conditions.
